

# Glide for Microsoft 365 Copilot

Testing instructions for Microsoft validation. Not shown to customers.

## What this agent does

Glide connects Microsoft 365 Copilot to a GlideOS workspace, where teams build and run internal business apps. The agent registers Glide's Model Context Protocol (MCP) server as an agent connector, so Copilot can create and manage projects, query and modify app databases, run workflows, publish apps, and read and write project files, all on behalf of the signed-in Glide user.

Tools are discovered from the server at runtime, so the tool list reflects what the server currently offers rather than a list frozen at submission.

## Test credentials

|              |                                |
|--------------|--------------------------------|
| Sign-in      | https://go.glideapps.com       |
| Email        | REPLACE_WITH_REVIEWER_EMAIL    |
| Password     | REPLACE_WITH_REVIEWER_PASSWORD |
| Organization | REPLACE_WITH_ORG_NAME          |

This account is an organization admin, so every tool is reachable. It is a dedicated sandbox: the data is invented and none of it is customer data.

**The account's plan matters.** Glide's MCP server is a paid plan feature. An account without it can sign in, but every tool call is refused. The account above has the feature enabled. No tenant-side setup, admin consent, or configuration is needed beyond installing the agent.

## Signing in

1. Open Microsoft 365 Copilot and select the **Glide** agent.
2. Ask any question about Glide data, for example the first prompt in the next section.
3. Copilot shows a **Sign in** card. Select it, sign in with the credentials above, and approve access.
4. When the popup closes, **ask the question again in the same chat, or start a new chat.** Copilot resolves its tool list when a chat begins, so a conversation that started before sign-in may still report having no tools. This is expected, not a fault.

A brief connecting state at the start of each new chat is also expected. That is the agent resolving its tools from the server for that session.

# What to test

The agent ships five conversation starters. Each returns real data in the test organization.

| Prompt                                                                                       | Expected result                                                                                                                                                                                                                                |
|----------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| List my Glide projects and tell me which ones have a published app.                          | One project, <b>Equipment Checkout</b> , containing a published app of the same name and an enabled workflow called <b>Overdue Sweep</b> . The agent distinguishes apps from headless workflows.                                               |
| Show me the tables in the database of my most recently created project.                      | Three tables ( <code>equipment</code> , <code>checkouts</code> , <code>overdue_reminders</code> ) and two views ( <code>equipment_availability</code> , <code>checkout_activity</code> ), each with a description read live from the database. |
| Which workflows are enabled in my most recently created project, and when did they last run? | <b>Overdue Sweep</b> , enabled, with its most recent run and a weekday schedule.                                                                                                                                                               |
| Are there any runtime errors in the current previews of my apps?                             | A clear report, whether or not errors exist.                                                                                                                                                                                                   |
| Create a new Glide project called Inventory Tracker.                                         | The agent describes the change and asks for confirmation before acting. See the next section.                                                                                                                                                  |

The first prompt. The agent reads the organization live and separates the published app from the headless workflow.

The second prompt. Table and view descriptions are read from the database at the moment of asking, not stored in the agent.

## Disclosure and confirmation for actions

The agent never changes data without stating what will change and getting explicit approval first.

Asked to create a project, the agent names the proposed change and waits. Nothing is created until the reviewer confirms.

The server independently refuses high-impact tools until a human approves that specific call: running shell scripts, running backend code, destructive SQL, database restores, deleting projects, and changing who can open an app. The agent cannot approve these on its own behalf.

Most tools that change data also accept a dry run, returning a plan instead of executing.

**Safe to exercise destructively.** The organization is a sandbox. Create, rename, and delete projects freely, write to the database, and run the workflow. Deleting the **Equipment Checkout** project would remove the data the prompts above rely on, so please delete only projects you create.

## Data handling

- Every call runs as the signed-in Glide user, inside their organization, subject to their role. The agent cannot reach another organization.
- Secret values are never returned. Listing secrets returns names and descriptions only.
- Every mutating call and every denied call is recorded in an audit log, queryable through the agent.
- File changes are recoverable, and database restores preserve the prior state first.

## Licensing

---

The agent is free to install. Using it requires a Glide plan that includes the MCP server feature, purchased from Glide rather than through Microsoft. This is declared under additional purchases and stated in the listing description. The test account above already has an eligible plan.
